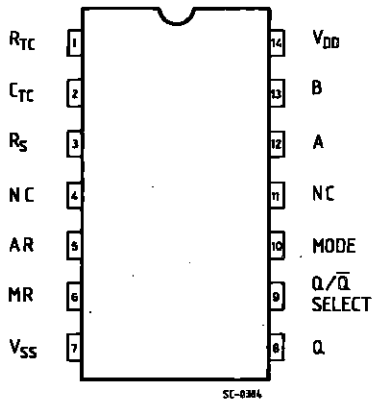
DESCRIPTION

The CC4541 is a monolithic integrated circuit fabricated in Metal Oxide Semiconductor technology available in DIP and SOP packages.
This device is composed of a 16-stages binary counter, an oscillator controlled by 2 external resistors and a capacitor, an output control logic and an automatic power-on reset circuit. The counter varies on positive-edge clock transition and it can be cleared by the MASTER RESET input. The output from this timer is the Q or $\overline{Q}$ output from the 8th, 13th, or 16th counter stage. The choice of the stage depends on the time

PIN CONNECTION



select inputs A or B (see frequency selection table). The output is available in one of the two modes that can be selected via the MODE input pin 10 (see truth table). The output turns out as a continuos square wave, with a frequency equal to the oscillator frequency divided by 2^N . When this MODE input is a logic "1", when it is a logic "0" and after a MASTER RESET is started, and Q output has been selected, the output goes up to a high state after 2^{N-1} counts. It remains in that state till another MASTER RESET pulse is apply or the mode input is a logic "1". The process starts by setting the AUTO RESET input (pin 5) to logic "0" and switching power on. If pin 5 is set to logic "1", the AUTO RESET circuit is not enabled and counting cannot start till a positive MASTER RESET pulse is applied, returning to a low level. The AUTO RESET consumes a remarkable amount of power and should not be used if low power operation is wanted. The frequency of the oscillator depends on the RC network. It can be calculated using the following formula :

$f = 1 / 2.3\ R_{TC}\ C_{TC}$

where f is between 1KHz and 100KHz and RS $\geq$ 10 KΩ and $\approx 2\ R_{TC}$
